[Experimental photoperiodic regulation of a circadian rhythm of eye movement activity in rats]. Mature male Wistar rats (200-220 g) exhibited the nocturnal activity pattern of the eyes (pursuit and rapid rotation) on the 2nd and the 8th day of the experiment. The 3-hour repetition of light pulses, with the peak of their duration between 23.30 and 00.30 of the 12th hour of the day, resulted in the regulation of the nocturnal rhythm of the eyes and the reduction of the pyriform factor (FE) and the level of the marker enzyme activities of the left frontal cortex. In the same time the intraseptal norepinephrine (NE) was increased in a dose-dependent manner; however, the circadian rhythm of the NE content in various structures of the brain was not changed. The regression analysis showed that the degree of the effects of photoperiodic regulation of the pursuit and rapid rotation activity was related to the length of the interval between the light and the dark phases of the photoperiod. return } try super.methodThatMightThrow() } } You could use the code above to use your class in this way: let i = FooClass() i.run() // this could throw print("Done") If you were using a more complex class, say with a protocol, and with methods that return structs, you could create a protocol: protocol SomeCoolProtocol { var n: Int {get} var d: Double {get} init() func doSmthgElse() } And then you would do as follows: class FooClass: SomeCoolProtocol { func run() throws { guard var n = try super.n() else { return } guard var d = try super.d() else { return } try super.doSmthgElse() return } init() { let x = n+d } } You could use this

## What's New in the Photoshop 2022 (version 23)?

In the late 1980s when the Soviet Union collapsed and people could wear their t-shirts and shorts freely, I remember my parents telling me that the “uncivilized” society of the USSR was having a major influence on my generation’s physical appearance, but that would change as soon as the Berlin Wall came down in 1989. A multidisciplinary research team led by a professor of neurology at the University of Turku in Finland has found that a single, short-term memory loss caused by scopolamine in a group of 15 young (average age 19.5 years) male subjects increased the odds of the participants committing a serious crime. Young people in the study had been deliberately manipulated by researchers into having memory problems that would mimic the brain damage of dementia. The four-month study was conducted in Finland between 2011 and

2013, and published in the New England Journal of Medicine. During the study, the subjects completed a series of 13 task sessions involving visual and verbal presentation of words and images. They were also given small doses of a drug that can be absorbed through the skin. The drug had no influence on the participants' mood or behaviour, but they reported having a "dull" and "fuzzy" feeling, an inability to perform some tasks, and a feeling of losing time. The drug seemed to impair the participants' short-term memory, possibly by disrupting the neurotransmitter acetylcholine, which helps transfer information to the brain. The study showed that, while already being at risk of offending, the participants were more likely to commit a crime in a period of three months following the study. The authors say they cannot yet determine whether the memory impairment alone caused the crime, but they do note: "We speculate that the relatively mild memory impairment present in scopolamine-treated subjects, without significant influences on the other cognitive functions, may have increased impulsivity and potentially sensitivity to situational cues." The authors add that further studies are required to assess whether "memory impairment in a nonclinical setting can act as a predisposing factor to unlawful behaviour."
